The epitaxial growth of pristine and Cobalt doped Anatase TiO$_2$ (Ti$_{1-x}$Co$_x$O$_2$, 0.02 < x < 0.08) on LaAlO$_3$ (100) has been carried out with goal of getting enhanced magnetic and better optical properties with good structural quality. We have grown pristine and cobalt doped Anatase TiO$_2$ thin films with MBE showing good crystalline nature as depicted by the RHEED images with slow growth rate taken over a substrate temperature of 600-650 K degree C on LaAlO$_3$ (100). Films were grown in the presence of molecular oxygen while previously reported growth of these oxide films were with OPMBE or by using ozone flux. Formation of smooth and single phase crystalline nature of the thin film is confirmed by XRD and AFM, EDS. Enhanced magnetism due to oxygen vacancies and doping of Co in the host lattice which is measured by SQUID and the temperature dependent magnetic measurements predicts the curie temperature just above the 300K. The photoconductivity measurements of these thin films gives the photosensitization of Anatase titania with transition metal dopants.
