# Baryon Acoustic Oscillations

- Pressure waves travel in hot early universe. Imprint characteristic scale on the galaxy distribution.
- Detected in 2005 by SDSS and 2dFGRS. SDSS detection from LRG sample.
- Physical scale determined by CMB constraints plus straightforward physics.
- Provides standard ruler 150 Mpc ( $100h^{-1}$  Mpc) long for measuring  $D_A(z)$  and  $H(z)$ .

$$D_A = L / \theta ; H = c \Delta z / L$$

# Baryon Acoustic Oscillations

- BAO imprint a “standard ruler” scale on the clustering of matter.
- Length ( $153.2 \pm 1.7$  Mpc) can be calculated given cosmological parameters measured by CMB anisotropies.
- Measurable in distribution of galaxies or intergalactic gas.
- Angular scale of oscillation peak yields  $D_A(z)$ .
- Line-of-sight scale yields  $H(z)$ .
